**Abstract - The Construction of High Rise structure is very common nowadays due to the fact that live able space is getting filled up due to ever increase in population and developments. The high rise structures pose a challenge for the structural engineers in regard to the selection and design of a suitable foundation system which efficiently fulfils the demand of the situation. The design of a suitable foundation depends upon a number of reasons like type of soil, zone, importance of the structure etc to name a few and this is a challenge for the structural engineers and geotechnical engineers as the design of a foundation system is a combination of the cooperation between the two departments. In this project, A live Project of a High Rise structure, being executed in Mumbai, Maharashtra is taken up for the study of modeling and analysis. The High Rise structure comprises of a total of 30 story containing 3 parking levels and other living floors consisting of 8 flats on each floor level. The purpose of this project is to get an exposure in modeling a High Rise structure and analyze it and design the foundation system that is best suitable for the proposed structure. The modeling and analysis is done using ETABS. Different foundation systems have been designed for the structure using SAFE. In this project, various parameters are studied and compared for different load cases. The Codes, IS 1893:2002 for earthquake analysis and IS 875:2015 for wind analysis has been extensively studied and used for specifying various parameters.**

**Keywords: High Rise Structure, Story Displacement, Time Period, Foundation systems.**

### **I. INTRODUCTION**

A high-rise building is a building that is usually defined by the altitude in a different way in different fields. High Rise structure can be used for one purpose or for more than one purpose combined. High-rise buildings have turn out a reality with the creation of the elevator systems and more plentiful building materials. High-Rise structures pose various design challenges for structural and geotechnical engineers, especially when the structures are located in an earthquake prone region. Rapid growth of population in urban communities, limited land space, Expensive land prices are few of the many reasons behind the need for constructing High-Rise structures and the trend that is being followed by both the developing and developed countries. Shear Walls are the structural Component specifically essential in tall structures that are subjected to wind and seismic forces to oppose the in-plane horizontal forces. They provide high amount of strength and stiffness in the direction of orientation. Shear wall significantly minimizes lateral sway and proves effective in reducing earthquake damage to a great extent in addition to many other advantages it has. The Foundation of a Structure is a Chief Component and can be described as the sub-structural segment which safely transfers the gravity loads to the earth transmits the gravity loads to the soil. Foundation for a structure is designed and constructed to distribute the loads of the structure over a big region to minimize excess loading of the earth beneath, to prevent unequal settlement, to increase the stability and resisting overloading etc. Different kind of foundation systems are designed as per the need and necessity.

The Main Objectives of the project work are:

- 1) To understand the commercially available structural modeling software, in which high rise buildings can easily be modeled. Example: ETABS, SAP2000.
- 2) To Model, analyze and design an existing high rise building, situated in Mumbai, Maharashtra.
- 3) The structure will be analyzed for Gravity, Earthquake and Wind loads in views of the respective Codal Provisions.
- 4) Choosing SAFE software for modeling, analyzing and designing the different types of foundation systems.

### **II. DESCRIPTION OF STRUCTURAL MODEL**

For the project, the structural model of a live project of a High Rise structure, being executed in Mumbai, is made. The High Rise building consists of a total of 30 floors consisting of 3 parking levels and other living floors with 8 flats on each floor. Storey height of parking levels is 3.5m and typical storey height is 3m. Slab thickness for parking levels and living floors is 150mm and 125mm respectively. Shear wall thickness is taken as 230mm, 300mm, 350mm at different locations. Wall thickness is 230mm. Density of concrete and masonry is taken as 25 kN/m<sup>3</sup> and 20 kN/m<sup>3</sup> respectively. Live load intensity for different spaces is applied as IS 875 Part-2. Concrete Grade mix is M30 and Grade of Rebar used

is Fe500. The building is considered to be located in Seismic zone III and it is founded on a medium strength soil. Response reduction factor is taken as 3. Importance factor is considered as 1. Wind speed is taken as 44. The values for Importance factor for wind, Risk Coefficient factor and Topography factor are all taken as 1. In seismic weight calculations, 50% of the floor live loads are considered.

Figure 6 Base Shear in longitudinal Direction

## VII. Raft Foundation System

Figure 7 Raft Foundation

In the proposed raft foundation system, the grade of concrete mix is taken as M40 and Grade of Rebar used is Fe550. The depth of the Raft is safe at 2000 mm. Soil Bearing Capacity (S.B.C) is taken as 500 kN/m<sup>2</sup> and 5 mm of Permissible Settlement is considered. The Deformed Shape is considered for Service loads Combination ( Dead Load + Live Load + Super Imposed Dead Load). The Maximum Displacement is -1.3265 mm and Minimum Displacement is -4.6391 mm and is within the Permissible Limits.

Figure 8 Deformed Shape

The Maximum Soil Pressure for Service Loads is  $463 \text{ kN/m}^2$ , which is less than the Soil Bearing Capacity of  $500 \text{ kN/m}^2$  and therefore, safe in bearing

Figure 9 Soil Pressure Diagram

### Punching Shear

Figure 10 Element Shell stress components considered in SAFE for Punching shear stress

When an observation is made, the shear stress components for the Raft evaluated (ie S12,S12,S23) are within permissible limits specified by the IS 456:2000. Hence , it can be concluded that the raft for the High Rise Building is safe against Punching Shear stress ( for top as well as the bottom face ).

Figure 17 Bottom Reinforcement in Y-Direction

TABLE 5 Reinforcement Details of Raft Foundation

| Thickness of Raft<br>(mm) | TOP REINFORCEMENT |                  | BOTTOM REINFORCEMENT |                  |
|---------------------------|-------------------|------------------|----------------------|------------------|
|                           | X-DIRECTION       | Y-DIRECTION      | X-DIRECTION          | Y-DIRECTION      |
| 2000                      | 25mm @ 150mm C/C  | 25mm @ 150mm C/C | 25mm @ 150mm C/C     | 25mm @ 150mm C/C |

### VIII. Pile Foundation

Figure 18 Pile Foundation

In This Foundation System, Grade of Concrete Mix is taken as M40 and Grade of steel is taken as Fe500. The Depth of Pile Cap is taken as 2000 mm. Diameter of Pile used is 750 mm. A Permissible Settlement of 5 mm is considered. The Deformed Shape is considered for Service loads Combination ( Dead Load + Live Load + Super Imposed Dead Load). The Maximum Displacement is -0.85 mm and Minimum Displacement is -9.19 mm and is within the Permissible Limits.

Figure 19 Deformed Shape

When an investigation is made, the shear stress components for the Piles determined ( ie S12,S13,S23 ) are within the permissible limits as specified by IS 456:2000. Therefore, it can be stated that the Pile Foundation for the High Rise building is safe against Punching Shear stress (for top and bottom faces).

TABLE 6 Reinforcement Details of Pile Cap

| Thickness of Pile Cap (mm) | TOP REINFORCEMENT |                  | BOTTOM REINFORCEMENT |                  |
|----------------------------|-------------------|------------------|----------------------|------------------|
|                            | X-DIRECTION       | Y-DIRECTION      | X-DIRECTION          | Y-DIRECTION      |
| 2000                       | 20mm @ 150mm C/C  | 20mm @ 150mm C/C | 25mm @ 150mm C/C     | 25mm @ 150mm C/C |

## IX. CONCLUSION

- The study of various parameters like Story displacement, story drift, modes, mode shapes, base shears has provided a more interest in the functionality of the structure and its performance.

- During the story displacement output, it is observed that the story displacement is maximum due to wind and therefore, wind analysis plays an important role in the analysis of the structure and special attention is required to analyze and design the structure so that it can efficiently resist these loads.
- The Mode vs Time period shows that the time period decreases with increase in modes and therefore, it is important to observe the modes and mode shapes of the structure.
- In the story drift result, it has been seen that story drift is maximum due to wind upto an extent of some floors and then, it is being overtaken by earthquake force.
